Windows handles are the way an application gets access to its system resources. Although they are not directly accessible to the user, they are essential for creating applications that can interact with each other and with the OS. Each application has a primary window that it can interact with, a concept that will be discussed further. The handle's internal representation looks as follows: `TypeInternal structure Type *handleHandleType = HANDLEPTR_TYPE * HandlePtrHandleTypeHANDLEHANDLE;` When a handle is opened, Windows assigns it a unique entry in the internal table of all handle entries. The table's internal structure is always displayed on the right, while the handle's internal structure is on the left, as shown here. This page will discuss how to view a Windows application's handles. *Due to the fact that Windows applications can support multiple handles, it is possible to open them simultaneously. For example, it is not uncommon for an application to open a parent window and a child window simultaneously, either side by side or one on top of the other. Each window has its own handle entry and thus can be referenced separately. Thus, although Windows applications can only have one handle open at a time, many more can be opened simultaneously. Of course, not all windows will support this feature, as most Windows applications are geared towards the Windows UI system. There are cases however where an application may allow multiple Windows handles to be opened at the same time, an instance being a Multiple Document Interface. These types of applications may allow the user to perform multiple tasks within the same application. Thus, for instance, an application that displays a program window and a data window at the same time would open multiple handles for each. However, they will only appear if the user actively selects the feature. If the user is not interested in it, there is no need to open multiple windows. This feature is turned on or off in the application properties or in the Windows registry. The main method for accessing handles is using the Spy++ utility. Spy++ is a freely available, Windows utility that provides users with the means to view the handles and files of an application. It features the most basic means of manipulating handles, including a type selector and a Windows Explorer window that displays each application's handles. Spy++ is available in the form of an installable application, as well as on the computer from which the handles can be viewed. Users must select

Handles are abstract references to specific system resources, for instance a document or a graphic image. Generally, a software utility does not have the capability of directly accessing an object's data, resorting in turn to handles. Windows' Application Programming Interface relies heavily on the use of handles for object representation, but also for their function as a communication pathway between the OS and the user. Each individual handle is assigned a unique entry in an internal table, featuring the address of the resource it refers to and the means to determine its type. Certain objects can support multiple handles, while others only support one at a time. WinFinder was based on Microsoft Spy++, providing users with a simpler means of displaying Windows handles, saving them valuable time and effort. In order to view a window's handles, users are required to click and drag the crosshair tool over a preferred window, then release it. WinFinder will emphasize the various Windows handle options using a red rectangle, so users can decide which item is of interest to them. Afterward, it will instantly retrieve the relevant information and display it for further analysis. The application offers information concerning the 'Current Window' properties, including the handle entry number and the caption, if available. It also features the name of the app on which the crosshair tool was dropped on, along with its class and the mouse position coordinates. Similarly, WinFinder will display these types of details about the 'Parent Window'. WinFinder is an intuitive utility that provides users with a quick means of displaying Windows handles and Application Programming Interfaces, helping them carry on with their work more efficiently. multiprocessing. The bottleneck is computation of simple mathematical function: `import math from multiprocessing import Pool def f(x): return x**2 + x - 3 if __name__ == '__main__': p = Pool() print p.map(f, range(3))` This code takes about 15s to run in parallel (yes, I timed it, just to prove my point). Now, I know that in some cases you can find work-arounds by tweaking other parts of your code. For example, a common way to bypassing long computations is to explicitly add numpy calls in the middle of the code. Question 1
